Simulation of Hydrodynamic Ram (HRAM) Phenomenon using MSC.Dytran Author: Yang Kangjie Roy

Advisor: Professor Young Kwon, Co-Advisor: Professor Christopher Adams

Objective

To develop a Finite Element model using MSC.Dytran to analyze the dynamic response of tank structure, and conduct parametric studies on factors that could affect

tank wall response during the initial phase of HRAM event

Model Description

The HRAM model consist of three main parts as shown in Figure 1: Lagrangian mesh for the tank and projectile and Eulerian mesh for the fluid inside the tank.

Research Results

Key features of HRAM phenomenon such as the shock wave propagation through the fluid upon impact (Figure 2), drag phase pressures (Figure 3), cavity evolution (Figure 4) and tank walls deformation (Figure 5) could be observed from the model.

Parametric studies were conducted with the model to investigate exit wall response to varying parameters such as Fluid Filling Levels, Fluid Density, Tank structure Material Modulus of elasticity, Tank structure Material Density, Projectile Weight and Projectile Velocity.

Of all the factors tested, Projectile velocity is found to have the strongest influence on the deformation of the exit wall. Damage to exit wall could be greatly reduced if the projectile velocity could be reduced significantly by the Material Properties: steel of mass 4g

200mm cubic tank discretised with 9,600 2-D four node Quadrilateral shell element Material Model: DMATEP (isotropic, elastoplastic material with a failure criterion) Material Properties: Aluminium thickness of 2mm

Fluid inside tank discretised with 64,000 eight nodes solid hexahedron Eulerian element Material Model: LINFLUID (linear fluid) Material Properties: Water

Benefit of the research

Provide a better understanding on the source and magnitude of the pressure waves generated in the fluid and the dynamic response of the coupled tank structure due to HRAM event. The ultimate goal of HRAM analysis and research is to design aircraft fuel tank structures to withstand HRAM loads, or to develop HRAM mitigation techniques so as to better protect aircraft and increase its survivability.
